**UNI
FREIBURG**

Based on

- ▶ [arXiv:1009.1127](https://arxiv.org/abs/1009.1127) (Höche, Krauss, Schönherr, FS)
- ▶ [arXiv:1008.5399](https://arxiv.org/abs/1008.5399) (Höche, Krauss, Schönherr, FS)
- ▶ [arXiv:0912.3501](https://arxiv.org/abs/0912.3501) (Höche, Schumann, FS)
- ▶ [arXiv:0903.1219](https://arxiv.org/abs/0903.1219) (Höche, Krauss, Schumann, FS)

LHC phenomenology

- ▶ Higgs/BSM signals with heavy particles decaying into high multiplicity final states
 - ▶ Backgrounds from simple SM processes with many additional jets
- ⇒ Need good understanding of higher order QCD corrections to SM processes

Typical theoretical approaches

1. Calculation to **fixed order** in α_s (e.g. NLO)

Born level matrix element

Virtual matrix element

Real emission matrix element

2. Approximate **resummation** of full series in α_s (e.g. parton shower)

This talk

Improving approximate resummation of this series with exact fixed order corrections

The POWHEG method

Results

Combining it all

The MENLOPS algorithm

Results

Monte-Carlo event generation

What are event generators?

- ▶ Simulation programs for collider physics
- ▶ Modelling of the complete hadronic final state
- ⇒ Work horses for theoretical interpretation of measurements

Basic principle

- ▶ Factorisation into event phases
- ▶ Perturbatively calculable:
 - ▶ Hard scattering
 - ▶ Initial state parton shower
 - ▶ Final state parton shower
 - ▶ (Multiple parton interactions)
- ▶ Non-perturbative modelling:
 - ▶ (Multiple parton interactions)
 - ▶ Hadronisation
 - ▶ Hadron decays

Central ingredient: Parton showers

Motivation

- ▶ Higher-order QCD corrections to hard scattering:
Infrared divergences from real/virtual cancel for inclusive quantities (\rightarrow KLN)
- ▶ But: Resolution through confinement of partons at $\mu_{\text{had}} \approx 1$ GeV (hadronisation)
 \Rightarrow Not inclusive
- ▶ Finite remainders of infrared singularities:
logarithms of ratio $\mu_F^2 / \mu_{\text{had}}^2$ with each $\mathcal{O}(\alpha_s)$
- ▶ Such large logarithms have to be resummed to all orders

Parton shower:

- ▶ Higher orders represented by parton branchings
- \Rightarrow Evolution of parton ensemble between μ_F^2 and μ_{had}^2

Question

How to get the (no-)branching probabilities to describe this evolution between different scales?

Construction of a parton shower (I/II)

Factorisation of QCD emissions

Universal factorisation of QCD real emission ME in soft/collinear limit:

$$\mathcal{R} \rightarrow \mathcal{B} \times \left(\sum_{ij,k \in \text{partons}} \frac{1}{2p_i p_j} 8\pi\alpha_s \mathcal{K}_{ij,k}(p_i, p_j, p_k) \right)$$

- ▶ \mathcal{B} Born matrix element
- ▶ Sum over subterms ij, k of the factorisation, e.g. parton lines (DGLAP) potentially with spectator k
- ▶ $\frac{1}{2p_i p_j}$ from massless propagator
Evolution variable of shower $t \sim 2p_i p_j$ (e.g. k_\perp , angle, ...)
- ▶ $\mathcal{K}_{ij,k}$ **splitting kernel** for branching $(ij) + k \rightarrow i + j + k$
Specific form depends on scheme of the factorisation above, e.g.:
 - ▶ Altarelli-Parisi splitting functions
 - ▶ Dipole terms from Catani-Seymour subtraction
 - ▶ Antenna functions
 - ▶ ...

Construction of a parton shower (II/II)

Differential (no-)branching probability

- ▶ Radiative phase space: $d\Phi_{\text{rad}}^{ij,k} = \frac{1}{16\pi^2} dt dz \frac{d\phi}{2\pi}$
- ▶ Combined with radiative part of the factorised ME (Jacobian/symmetry factor/PDFs ignored)

$$d\sigma_{\text{rad}}^{ij,k} = \frac{dt}{t} dz \frac{d\phi}{2\pi} \frac{\alpha_s}{2\pi} \mathcal{K}_{ij,k} \quad \text{Differential branching probability}$$

No-branching probability

Above: Differential probability for **one** branching to (not) happen in interval dt

Goal: Total no-branching probability between scale t' and t''

- ▶ **Integrate** over z, ϕ , and t from t' to t''
- ▶ Assume **multiple independent** emissions (Poisson statistics) \Rightarrow **Exponentiation**

$$\text{subterm: } \Delta_{ij,k}(t', t'') = \exp \left\{ - \sum_{f_i=q,g} \int_{t'}^{t''} \frac{dt}{t} \int_{z_-}^{z_+} dz \int_0^{2\pi} \frac{d\phi}{2\pi} \frac{\alpha_s}{2\pi} \mathcal{K}_{ij,k}(z, t) \right\}$$

$$\text{event: } \Delta(t', t'') = \prod_{ij,k} \Delta_{ij,k}(t', t'')$$

Master formula

Cross section up to first emission in a parton shower

$$\sigma = \int d\Phi_B B \left[\underbrace{\Delta(t_0, \mu^2)}_{\text{unresolved}} + \underbrace{\sum_{ij,k} \frac{1}{16\pi^2} \int_{t_0}^{\mu^2} dt \int_{z_-}^{z_+} dz \int_0^{2\pi} \frac{d\phi}{2\pi} \Delta(t, \mu^2) \frac{8\pi\alpha_s}{2p_i p_j} \mathcal{K}_{ij,k}(z, t)}_{\text{resolved}} \right]$$

Features

- ▶ LO weight B for Born-like event
- ▶ Unitariness: Term in square brackets $[\dots] = 1 \Rightarrow$ LO cross section preserved
- ▶ “Unresolved” part: No emissions above parton shower cutoff t_0
- ▶ “Resolved” part: Emission between t_0 and factorisation scale μ^2
- ▶ Emission in parton shower approximation with $\mathcal{K}_{ij,k}$

Canonical Example: Drell-Yan process $pp \rightarrow \ell\ell$

Transverse momentum of the lepton pair

Transverse momentum of the third jet

Conclusions

- ▶ $p_{\perp}^{\ell\ell}$ probes QCD emissions because of recoil
- ▶ Resummation avoids divergence of fixed order calculation for $p_{\perp}^{\ell\ell} \rightarrow 0$
- ▶ Hard QCD emissions (leading to $p_{\perp}^{\ell\ell} > \mu_F \approx m_Z$) not well described (as we will see later)
- ▶ Factor $K = 1.2$ to compare to NLO results later

Main idea of ME+PS merging

Phase space slicing for QCD radiation in shower evolution

- ▶ **Hard emissions** $Q_{ij,k}(z, t) > Q_{\text{cut}}$
 - ▶ Events rejected
 - ▶ Compensated by events starting from higher-order ME (regularised by Q_{cut})

⇒ Splitting kernels replaced by exact real emission matrix elements

$$\frac{8\pi\alpha_s}{2p_i p_j} \mathcal{K}_{ij,k}(z, t) \rightarrow \frac{8\pi\alpha_s}{2p_i p_j} \mathcal{K}_{ij,k}^{\text{ME}}(z, t) = \frac{\mathcal{R}_{ij,k}}{\mathcal{B}}$$

- ▶ **Soft/collinear emissions** $Q_{ij,k}(z, t) < Q_{\text{cut}}$
 - ⇒ Retained from parton shower $\mathcal{K}_{ij,k}(z, t) = \mathcal{K}_{ij,k}^{\text{PS}}(z, t)$

Note

- ▶ Boundary determined by “jet criterion” $Q_{ij,k}$
 - ▶ Has to identify soft/collinear divergences in MEs, like jet algorithm
 - ▶ Otherwise arbitrary, but some choices better than others
- ▶ In both regions: No-branching probabilities still from shower

$$\Delta(t', t'') \rightarrow \Delta^{(\text{PS})}(t', t'')$$

Master formula

Cross section up to first emission in ME+PS

$$\sigma = \int d\Phi_B B \left[\underbrace{\Delta^{(\text{PS})}(t_0, \mu^2)}_{\text{unresolved}} + \sum_{ij,k} \frac{1}{16\pi^2} \int_{t_0}^{\mu^2} dt \int_{z_-}^{z_+} dz \int_0^{2\pi} \frac{d\phi}{2\pi} \Delta^{(\text{PS})}(t, \mu^2) \right. \\ \left. \times \left(\underbrace{\frac{8\pi \alpha_s}{2p_i p_j} \mathcal{K}_{ij,k}^{(\text{PS})}(z, t) \Theta(Q_{\text{cut}} - Q_{ij,k})}_{\text{resolved, PS domain}} + \underbrace{\frac{R_{ij,k}}{B} \Theta(Q_{ij,k} - Q_{\text{cut}})}_{\text{resolved, ME domain}} \right) \right]$$

Features

- ▶ LO weight B for Born-like event
- ▶ Unitarity slightly violated due to mismatch of $\Delta^{(\text{PS})}$ and R/B
[...] $\approx 1 \Rightarrow$ LO cross section only approximately preserved
- ▶ Unresolved emissions as in parton shower approach
- ▶ Resolved emissions now **sliced** into PS and ME domain
- ▶ Only for one emission here, but possible **up to very high number** of emissions

Canonical Example: Drell-Yan process $pp \rightarrow \ell\ell$

Transverse momentum of the lepton pair

Transverse momentum of the third jet

Canonical Example: Drell-Yan process $pp \rightarrow \ell\ell$

Transverse momentum of the lepton pair

Transverse momentum of the third jet

Conclusions

- ▶ Multiple hard emissions properly accounted for
- ▶ Resummation preserved
- ▶ Inclusive rate still at LO \Rightarrow factor $K = 1.2$ necessary

Results: Features and shortcomings

Example

Diphoton production at Tevatron

- ▶ Recently published by DØ [Phys.Lett.B690:108-117,2010](#)
- ▶ Isolated hard photons with:
 - ▶ $E_{\perp}^{\gamma^1} > 21$ GeV
 - ▶ $E_{\perp}^{\gamma^2} > 20$ GeV
 - ▶ $|\eta_{\gamma}| < 0.9$
 - ▶ Isolation: $E_{\perp}(R = 0.4) - E_{\perp}^{\gamma} < 2.5$ GeV
- ▶ Here: Azimuthal angle between the diphoton pair

ME+PS simulation using SHERPA 1.2.2 with QCD+QED interleaved shower and merging

Höche, Schumann, FS (2010)

Conclusions

Shapes described very well even for this non-trivial process/observable for both:

- ▶ Hard region, e.g. $\Delta\Phi_{\gamma\gamma} \rightarrow 0$
- ▶ Soft region, e.g. $\Delta\Phi_{\gamma\gamma} \rightarrow \pi$

Total cross section too low \Rightarrow Virtual MEs needed

The POWHEG method

Motivation

- ▶ Parton shower for resummation ✓
- ▶ ME+PS for correct hard radiation pattern ✓
- ▶ Inclusive rate still at LO in α_s ... can we do **NLO + parton shower?**
 - ▶ MC@NLO Frixione, Webber (2002)
 - ▶ POWHEG Nason (2004), Frixione, Nason, Oleari (2007) (used in the following)

Two issues to solve

1. Cross section at NLO accuracy in α_s
2. Radiation pattern of first emission according to real ME

Note

- ▶ Completely orthogonal to and independent of ME+PS merging
- ▶ Only possible for first emission, not for higher orders

Cross section at NLO accuracy in α_s

Reminder: Matrix elements contributing to NLO

- ▶ **Born ME** → automatic tree-level generators
- ▶ **Virtual ME** → dedicated codes, Binoth Les Houches interface
- ▶ **Real emission ME** → automatic tree-level generators

Integrating over real emission phase space

- ▶ **Problem:** Cancellation of infrared divergences between virtual and real, Separate numerical integration (N and $N + 1$ final states) not possible
- ▶ **Solution:** Subtraction procedure, e.g. Catani-Seymour or Frixione-Kunszt-Signer
 - ▶ Subtract universal divergent terms from real ME (**S**)
 - ▶ Integrate them analytically and add to virtual ME (**I**)
 - ⇒ Poles cancel
- ▶ Integration of real emission phase space explicitly or by Monte-Carlo sampling
- ⇒ NLO weight for event with Born level kinematics

$$\bar{B} = B + V + I + \sum_{\{\bar{i}_j, \bar{k}\}} \sum_{f_i=q,g} \int d\Phi_{R|B}^{ij,k} \left[R_{ij,k} - S_{ij,k} \right]$$

Radiation pattern of first emission

Matrix element corrections in parton showers

- ▶ Well-known method for reinstating $\mathcal{O}(\alpha_s)$ accuracy in parton shower radiation pattern
- ▶ Feasible only for simple cases

Reweighting principle (simplified)

- ▶ From above: weight with which to correct one emission

$$w_{ij,k} = \frac{d\sigma_{\text{rad}}^{ij,k}}{d\sigma_{\text{rad}}^{(\text{PS})ij,k}} = \frac{2 p_i p_j}{8\pi \alpha_s} \frac{\mathcal{R}_{ij,k}}{\mathcal{B} \mathcal{K}_{ij,k}}.$$

- ▶ Determine overestimate W_{ij} for the total weight throughout real-emission phase space
- ▶ Replace splitting kernels in parton shower $\mathcal{K}_{ij,k} \rightarrow W_{ij} \mathcal{K}_{ij,k}$
- ▶ Accept shower branchings only with probability w/W

Master formula

Cross section up to first emission in POWHEG

$$\sigma = \int d\Phi_B \bar{B} \left[\underbrace{\Delta^{(\text{ME})}(t_0, \mu^2)}_{\text{unresolved}} + \underbrace{\sum_{ij,k} \frac{1}{16\pi^2} \int_{t_0}^{\mu^2} dt \int_{z_-}^{z_+} dz \int_0^{2\pi} \frac{d\phi}{2\pi} \Delta^{(\text{ME})}(t, \mu^2) \frac{R_{ij,k}}{B}}_{\text{resolved}} \right]$$

Features

- ▶ NLO weight \bar{B} for Born-like event
- ▶ Unitarity: Term in square brackets $[\dots] = 1$
 \Rightarrow NLO cross section preserved
- ▶ First resolved emission exact according to real emission ME
- ▶ No-branching probability $\Delta^{(\text{ME})}(t_0, \mu^2)$ from R/B instead of \mathcal{K}
- ▶ Only one corrected emission, further emissions in parton shower approximation

Canonical Example: Drell-Yan process $pp \rightarrow \ell\ell$

Transverse momentum of the lepton pair

Transverse momentum of the third jet

Canonical Example: Drell-Yan process $pp \rightarrow \ell\ell$

Transverse momentum of the lepton pair

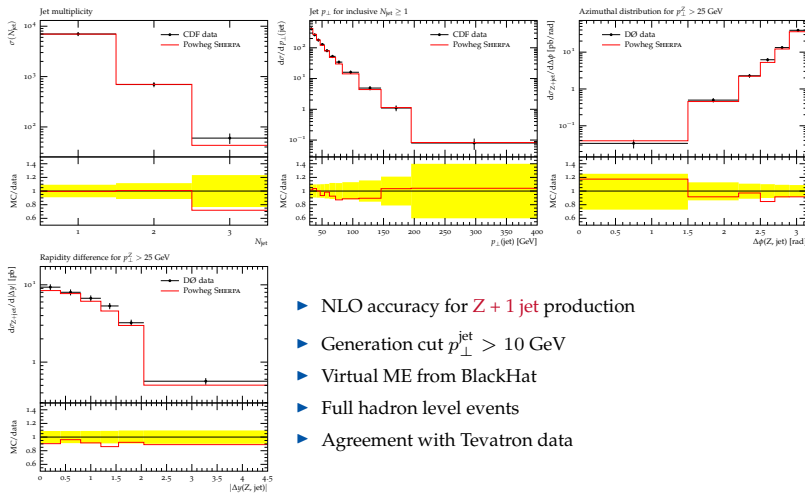

Transverse momentum of the third jet

Conclusions

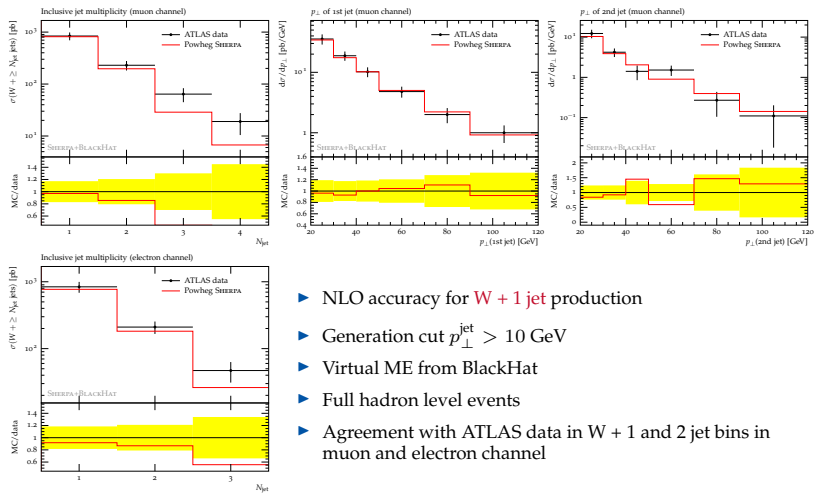

- ▶ Inclusive rate at NLO \Rightarrow no K -factor necessary
- ▶ First hard emission properly accounted for
 - \Rightarrow Observables sensitive to first emission (e.g. $p_{\perp}^{\ell\ell}$) fine
- ▶ Further emissions only in parton shower approximation
 - \Rightarrow Observables sensitive to higher order corrections not sufficiently described

State-of-the-art sneak preview: POWHEG for Z + jet

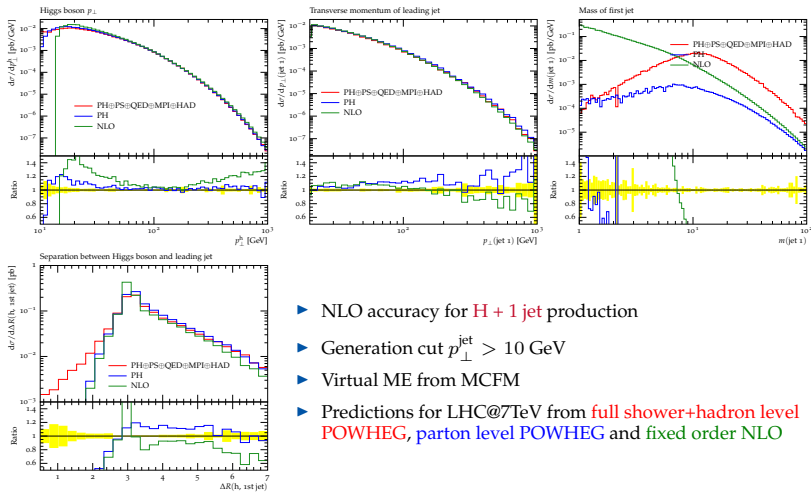

- ▶ NLO accuracy for Z + 1 jet production
- ▶ Generation cut $p_{\perp}^{jet} > 10$ GeV
- ▶ Virtual ME from BlackHat
- ▶ Full hadron level events
- ▶ Agreement with Tevatron data

State-of-the-art sneak preview: POWHEG for W + jet

- ▶ NLO accuracy for **W + 1 jet** production
- ▶ Generation cut $p_{\perp}^{\text{jet}} > 10$ GeV
- ▶ Virtual ME from BlackHat
- ▶ Full hadron level events
- ▶ Agreement with ATLAS data in W + 1 and 2 jet bins in muon and electron channel

State-of-the-art sneak preview: POWHEG for Higgs + jet

- ▶ NLO accuracy for **H + 1 jet** production
- ▶ Generation cut $p_{\perp}^{\text{jet}} > 10$ GeV
- ▶ Virtual ME from MCFM
- ▶ Predictions for LHC@7TeV from **full shower+hadron level POWHEG**, **parton level POWHEG** and **fixed order NLO**

The MENLOPS algorithm

Motivation

Two different methods to improve parton showers:

- ▶ POWHEG
 - + NLO accuracy in cross section
 - + First emission according to real emission ME
 - + Soft/collinear resummation from parton shower
 - Further hard emissions in parton shower approximation
- ▶ ME+PS
 - Only LO accuracy in cross section
 - + Soft/collinear resummation from parton shower
 - + All hard emissions according to real emission ME

Can we combine both methods and get rid of their disadvantages?

Idea starting from ME+PS

(see also Hamilton, Nason (2010))

- ▶ Replace “unresolved” and “PS resolved” part in ME+PS with POWHEG
i.e. run POWHEG generator instead of normal parton shower for first emission
- ▶ Generate “resolved ME” part separately through real emission MEs as before
- ▶ Supply real ME events with local K -factor $\frac{\bar{\sigma}}{\sigma}$
formally beyond NLO, but necessary for smooth merging

Master formula

Cross section up to first emission in MENLOPS

$$\sigma = \int d\Phi_B \bar{B} \left[\underbrace{\Delta^{(\text{ME})}(t_0, \mu^2)}_{\text{unresolved}} + \sum_{ij,k} \frac{1}{16\pi^2} \int_{t_0}^{\mu^2} dt \int_{z_-}^{z_+} dz \int_0^{2\pi} \frac{d\phi}{2\pi} \frac{R_{ij,k}}{B} \right. \\ \left. \times \left(\underbrace{\Delta^{(\text{ME})}(t, \mu^2) \Theta(Q_{\text{cut}} - Q_{ij,k})}_{\text{resolved, PS domain}} + \underbrace{\Delta^{(\text{PS})}(t, \mu^2) \Theta(Q_{ij,k} - Q_{\text{cut}})}_{\text{resolved, ME domain}} \right) \right]$$

Features

- ▶ NLO weight \bar{B} for Born-like event
- ▶ Unitarity still slightly violated: $[\dots] \approx 1$
 \Rightarrow NLO cross section only approximately preserved
- ▶ R events generated separately (not through POWHEG)
 \Rightarrow has to be supplemented with local $\frac{\bar{B}(\Phi_B)}{B(\Phi_B)}$ explicitly to reproduce the above

Canonical Example: Drell-Yan process $pp \rightarrow \ell\ell$

Transverse momentum of the lepton pair

Transverse momentum of the third jet

Canonical Example: Drell-Yan process $pp \rightarrow \ell\ell$

Transverse momentum of the lepton pair

Transverse momentum of the third jet

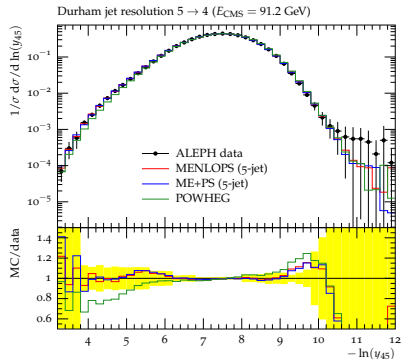

Conclusions

Jack-of-all-trades algorithm

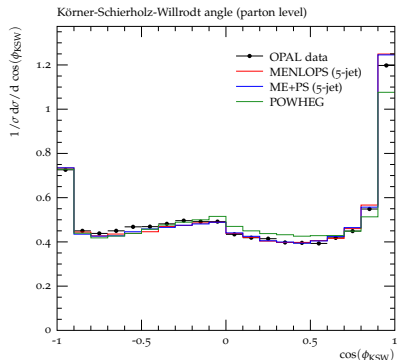

- ▶ Inclusive rate at NLO \Rightarrow no K -factor necessary
- ▶ Multiple hard emissions properly accounted for

Conclusions and outlook

Conclusions

- ▶ Tree-level ME+PS merging works well for shapes, but needs K -factor for cross section
- ▶ POWHEG reproduces full NLO cross section and shape of first emission but fails for additional hard radiation
- ▶ Combination of full NLO and higher order tree-level MEs with shower achieves both of the above
- ▶ Recently much progress and already first implementations
- ▶ Automated and publically available within SHERPA framework
- ▶ Inclusive merging only with NLO in core process, not in higher jet multiplicities ...

Outlook

- ▶ ...yet
- ▶ Unweighted event generation
- ▶ Application to more processes
